Working at Google - good idea?

You meet Sergey Brin

You've been hired at Google to run their **Life Sciences division**, congratulations! On your first day after your move to California's Silicon Valley, **Sergey Brin** comes in to meet the new wizard pythonista. He gets talking and admits to you there's so many googlers that he just cannot keep track of all of them. But he would like to build a rolodex of **central** googlers. Not just central in terms of titles or degrees or awards, but central in terms of social connections. Sergey wants you to find out who the most *social* googlers are.

Sergey has an idea: He gives you a list of projects that googlers have worked on, a list of Cruises googlers have gone on together, and a list of sport clubs users belong to.

You get 3 excel files:
1) `gprojects` are the projects googlers have worked on. The first column is the name of google employees, the subsequent columns are the projects that they have worked on. Googlers love codes, so the projects are encoded as sentences of ***four*** words each. The sentences don't need to make sense.
2) `gcruises` are the cruises that googlers have gone on. each row has the name of the google employee in the first column, and then the cruises she has been on. Cruises are encoded as sentences of ***three*** words each.
3) `gsports` are the sport clubs that googlers belong to. The first column contains googler employee name, subsequent columns the sport clubs they belong to. Sport clubs are encoded as ***two*** words.

Ok, so now you have list of googlers and projects, cruises, and sports in common. You may assume that if any two googlers have worked on the same project, gone on the same cruise, or played the same sport, they are ***connected***. In other words, acquainted with each other.

Sergey Brin tells you he'll be back in a few hours to check on your work. You think to yourself *great, he's testing me* :-(. Fresh from your python class at Harvard Extension, you open the lid of your laptop, fire up a jupyter notebook, and dive in!

This is what Sergey Brin is asking you to figure out:

Part 1.

1. a) Read in the three excel files provided as panda dataframes. Hint: you might need to install the xlrd package to get excel support. List Ian Isla's projects, cruises, and sport clubs at Google. Find *one* google employee that is connected with Isla because he or she has been on the same project, cruise, or sport club. **(10 points)**

   b) Find the total number of connections at Google. We define connections as pairs of googlers that worked on a project together, had a cruise together or participated in a sports club together. For example, if Ian Isla and Kaleb Lauren went on a cruise together, then (Ian Isla, Kaleb Lauren) represents a connection. Similarly, if Kaleb Lauren and Roman Valentina played a sport together, then (Kaleb Lauren, Roman Valentina) represents a connection. Furthermore, if Ian Isla and Kaleb Lauren worked on a project together, they have another connection as well. Thus, we have another (Ian Isla, Kaleb Lauren) connection. For this problem, it might help to assign ID's to all your google employees and then loop through projects, cruises and sports to find all possible connections. **(15 points)**

   c) Create a connections dictionary where for each googler, we store a list of all connections they participate in. Using this dictionary, determine the average number of connections per googler. **(15 points)**

d) Make use of this dictionary to find the most connected googler. What about the 10 *most* connected googlers? What about the 10 *least* connected googlers? What's the total number of connections, and the average number of connections at Google? Note that connections only counts number of projects, cruises, or sports in common. Who one is connected to makes no difference. A connection to Sergey Brin himself counts the same as a connection to a student co-op. **(10 points)**

Now, what if having important connections is of significance? In other words, being connected to Sergey Brin makes a huge difference: if a googler acquaintance you are connected to is *very* connected, that automatically makes you very ***central*** to google. To answer these questions, we need our old friend PageRank.

e) One possible way to tap into PageRank is to use the now-familiar package `networkx`. We want you to create a graph from our connections dictionary. Hint: There are many ways of doing this. One possible way involves hooking into the networkx method `parse_adjlist` that takes in an adjacency list(connections). Look up documentation on this function to learn more. **(10 points)**

f) Use the template from the midterm and previous assignments, or just use networkx's `pagerank()` API that professor mentionned in class to calculate pageRank for google employees. Using this information, find the 10 most central googlers, and the 10 least central googlers. Are they the same as the 10 most and 10 least connected googlers? **(10 points)**

g) BONUS: Can you plot google's connectome? That connectome should easily reveal the least central googlers, since they represent isolated nodes, far away from network traffic. You have some latitude on how you choose to do this. Can you do something to upend that graph to also easily reveal the most central googlers? **(5 points)**

You meet Larry Page

While you're pondering, Larry Page comes by your desk. He says wants to see even more connected googlers, and asks you to design a googler-you-may-know recommendation engine.

You think to yourself that... just maybe googlers might be otherwise (undocumentedly) connected with connections of their connections (outside of projects, cruises, and sports clubs)! So you decide to write some python to assemble connections of connections.

Part 2.

2. a) Write a list comprehension (ideally) or some type of loop to determine connections of connections. Essentially, you should already have a list of connections, but now search the connections of a specific googler to find connections of connections. For example, if (Ian Isla, Kaleb Lauren) were connected in Part 1, and (Kalen Lauren, Roman Valentina) were also connected, then Roman Valentina would be a "connection of a connection" of Ian Isla. While you do this, perform a check to ensure that the connection of a connection should not already be a connection itself. **(20 points)**

   b) What's the average number of connections-of-connections at google? You will be surprised to find out that even with only 3,000 employees, and just a few projects, cruises, and sports in common, the number of connections$^{2\,2}$ is huge. So, it would take forever to iterate through all possible employees. DON'T DO THIS. Instead, just use a random sampling technique to *sample* through a fraction of employees, throw in some debugging print statements in your loop(s) to see how fast your sampling is progressing, produce a few random samplings and average over these samplings. We leave it up to you how many samples you decide to choose, and will be lenient with our grading as long as your procedure seems reasonable. **(10 points)**

c) BONUS: What's the average distance that separates any two googlers? You may want to read this (http://blogs.cornell.edu/info2040/2011/09/26/networks-in-hollywood-the-six-degrees-of-kevin-bacon/) article about Kevin Bacon. This (https://en.wikipedia.org/wiki/Erd%C5%91s%E2%80%93Bacon_number) is a funny article, too. **(5 points)**

Congratulations! A successful first day at Google! You've made both Sergei and Larry happy. You're on your way to the top of the ladder! Exhausted, you escape from your desk before any other VP of soemthing can ask anything else from you, and stop for some sushi and a little jug of warm sake. Tomorrow is new employee orientation, and you're looking forward to introduce yourself to the most connected googlers. Now *that's* taking advantage of insider information!

Solutions: Part 1

***Note:* This solution analyzes Question 1 and 2 by partitioning the datasets. See FULL version for solution to Question 1. Each cell here can be executed for demonstration purposes.**

a) Read in the three excel files provided as panda dataframes. Hint: you might need to install the xlrd package to get excel support. List Ian Isla's projects, cruises, and sport clubs at Google. Find *one* google employee that is connected with Isla because he or she has been on the same project, cruise, or sport club. **(10 points)**

                break

print("Count of Connections from Sports Clubs: "+str(sportsCount))
print("Count of Connections from Cruises: "+str(cruisesCount))
print("Count of Connections from Projects: "+str(projectsCount))
```

```
Count of Connections from Sports Clubs: 622
Count of Connections from Cruises: 230
Count of Connections from Projects: 90
```

c) Create a connections dictionary where for each googler, we store a list of all connections they participate in. Using this dictionary, determine the average number of connections per googler. **(15 points)**

In [108]:

```
#Dictionary created as a part of Part B
dict
```

Out[108]:

```
{'Ian Isla': [['Ian Isla', 'Roman Valentina'],
  ['Ian Isla', 'Christian Alaina'],
  ['Ian Isla', 'Emmett Aurora'],
  ['Ian Isla', 'Angel Addison'],
  ['Ian Isla', 'Jake Arianna'],
  ['Ian Isla', 'George Bella'],
  ['Ian Isla', 'Hudson Melanie'],
  ['Ian Isla', 'Emmett Riley'],
  ['Ian Isla', 'Wesley Athena'],
  ['Ian Isla', 'Ashton Quinn'],
  ['Ian Isla', 'Luca Adriana'],
  ['Ian Isla', 'Aiden Sarah']],
 'Roman Valentina': [['Roman Valentina', 'Emmett Aurora'],
  ['Roman Valentina', 'Hudson Melanie'],
  ['Roman Valentina', 'Emmett Riley'],
  ['Roman Valentina', 'Wesley Athena'],
  ['Roman Valentina', 'Ashton Quinn'],
  ['Roman Valentina', 'Timothy Mckenzie']],
```

In [326]:

```
total = sportsCount + cruisesCount + projectsCount
count = len(dict.keys())
average = total/count
print("Average Connections: "+str(average))
```

```
Average Connections: 9.42
```

d) Make use of this dictionary to find the most connected googler. What about the 10 *most* connected googlers? What about the 10 *least* connected googlers? What's the total number of connections, and the average number of connections at Google? Note that connections only counts number of projects, cruises, or sports in common. Who one is connected to makes no difference. A connection to Sergey Brin himself counts the same as a connection to a student co-op. **(10 points)**

In [327]:

```
print("Total Connections: "+str(total))
print("Average Connections: "+str(average))
```

```
Total Connections: 942
Average Connections: 9.42
```

In [297]:

```
#Use bubble sort from our lectures, but modify it to work with a list of tuples so t
#we can order key-value pairs from greatest to least

```
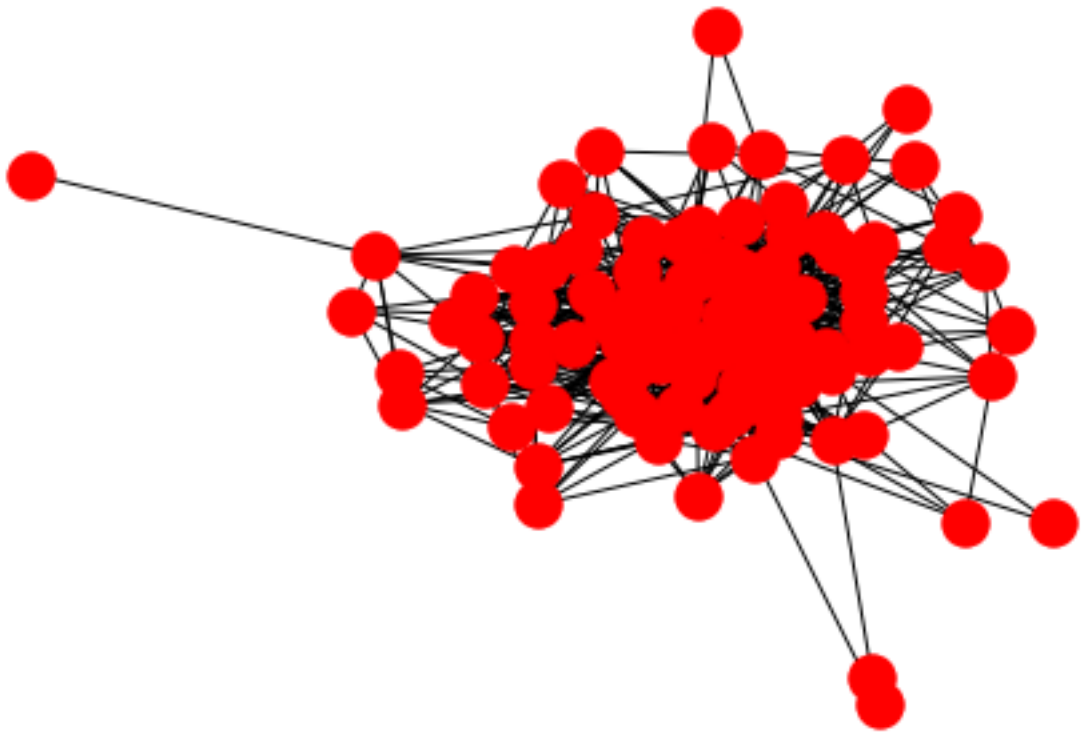
import networkx as nx

#Append the employeeIDs to create a list of strings (e.g. ['1 2 3', '2 2']) with key
test = []
for key, value in sorted(dictID.items()):
    test.append(str(key)+" "+" ".join([str(item) for item in value if item]))

#https://networkx.github.io/documentation/networkx-1.10/reference/generated/networkx
ggraph = nx.parse_adjlist(test, nodetype=str)
```

In [303]:

```
#Graph of Connections Drawn Out!
nx.draw(ggraph)
```



f) Use the template from the midterm and previous assignments, or just use networkx's `pagerank()` API that professor mentionned in class to calculate pageRank for google employees. Using this information, find the 10 most central googlers, and the 10 least central googlers. Are they the same as the 10 most and 10 least connected googlers? **(10 points)**

In [304]:

```
import numpy as np

#Apply PageRank to the graph of Googlers
ggraph_pr = nx.pagerank(ggraph) #Note: Default damping is 0.85!

#Convert the dictionary to a tuple and sort
ggraph_ranked = [(k, v) for k, v in ggraph_pr.items()]
bubble_sort(ggraph_ranked)
```

In [305]:

```
#Redo Part D to sort with EmployeeID rather than Employee names
empID_connections = []
for key, value in sorted(dictID.items()):
    empID_connections.append((key, len([item for item in value if item])))
bubble_sort(empID_connections)
```

In [306]:

```
#Top Ten Googlers by PageRank!
#Reference Pandas Table for Full Names associated with EmployeeIDs
ggraph_ranked[:10]
```

Out[306]:

```
[('50', 0.0228201294024106 72),

```

Out[309]:

```
[(97, 6),
 (91, 5),
 (94, 5),
 (64, 4),
 (57, 3),
 (15, 2),
 (80, 2),
 (44, 1),
 (53, 1),
 (72, 1)]
```

Note: We can see that the top and bottom pagerank and connected employee list are different (as we have noticed in class before) in that the top members of pagerank are not the same as the top members with the most connections. Those with connections indirectly others with MORE connections often increases the pagerank more - although there is much overlap between the top ten groups. Given the analogy of Sergey Brin previously - a connection to Sergey Brin at this point raises a person's pagerank more than a connection to a co-op student (assuming the co-op student has very few connections in turn) so it is more of a measure of importance!

g) BONUS: Can you plot google's connectome? That connectome should easily reveal the least central googlers, since they represent isolated nodes, far away from network traffic. You have some latitude on how you choose to do this. Can you do something to upend that graph to also easily reveal the most central googlers? **(5 points)**

In [ ]:

```
```

Solutions: Part 2

a) Write a list comprehension (ideally) or some type of loop to determine connections of connections. Essentially, you should already have a list of connections, but now search the connections of a specific googler to find connections of connections. For example, if (Ian Isla, Kaleb Lauren) were connected in Part 1, and (Kalen Lauren, Roman Valentina) were also connected, then Roman Valentina would be a "connection of a connection" of Ian Isla. While you do this, perform a check to ensure that the connection of a connection should not already be a connection itself. **(20 points)**

```

b) What's the average number of connections-of-connections at google? You will be surprised to find out that even with only 3,000 employees, and just a few projects, cruises, and sports in common, the number of connecti^{2} ^{2} is huge. So, it would take forever to iterate through all possible employees. DON'T DO THIS. Instead, just use a random sampling technique to *sample* through a fraction of employees, throw in some debugging print statements in your loop(s) to see how fast your sampling is progressing, produce a few random samplings and average over these samplings. We leave it up to you how many samples you decide to choose, and will be lenient with our grading as long as your procedure seems reasonable. **(10 points)**

In [340]:

```
#Since I am only beginning with a small subset of the original dataset, it is much e
total = secondCount

#Not everyone would presumably have secondary connections, so we use the original ar
countAll = len(dict.items())
averageAll = total/countAll

#Only out of the pool of people with secondary connections
countSeconds = len(secondConn.items())
averageSeconds = total/countSeconds

print("Average Secondary Connections (Amongst Everyone): "+str(averageAll))
print("Average Secondary Connections (Only Amongst Googlers With Secondary Connectio
```

```
Average Secondary Connections (Amongst Everyone): 32.14
Average Secondary Connections (Only Amongst Googlers With Secondary Co
nnections): 32.14
```

Note: in this case everyone has a secondary connection - but that is not neccessarily true!

c) BONUS: What's the average distance that separates any two googlers? You may want to read this (http://blogs.cornell.edu/info2040/2011/09/26/networks-in-hollywood-the-six-degrees-of-kevin-bacon/) article about Kevin Bacon. This (https://en.wikipedia.org/wiki/Erd%C5%91s%E2%80%93Bacon_number) is a funny article, too. **(5 points)**

In [ ]:

```
```

Working at Google - good idea?

You meet Sergey Brin

You've been hired at Google to run their **Life Sciences division**, congratulations! On your first day after your move to California's Silicon Valley, **Sergey Brin** comes in to meet the new wizard pythonista. He gets talking and admits to you there's so many googlers that he just cannot keep track of all of them. But he would like to build a rolodex of **central** googlers. Not just central in terms of titles or degrees or awards, but central in terms of social connections. Sergey wants you to find out who the most *social* googlers are.

Sergey has an idea: He gives you a list of projects that googlers have worked on, a list of Cruises googlers have gone on together, and a list of sport clubs users belong to.

You get 3 excel files:
1) `gprojects` are the projects googlers have worked on. The first column is the name of google employees, the subsequent columns are the projects that they have worked on. Googlers love codes, so the projects are encoded as sentences of ***four*** words each. The sentences don't need to make sense.
2) `gcruises` are the cruises that googlers have gone on. each row has the name of the google employee in the first column, and then the cruises she has been on. Cruises are encoded as sentences of ***three*** words each.
3) `gsports` are the sport clubs that googlers belong to. The first column contains googler employee name, subsequent columns the sport clubs they belong to. Sport clubs are encoded as ***two*** words.

Ok, so now you have list of googlers and projects, cruises, and sports in common. You may assume that if any two googlers have worked on the same project, gone on the same cruise, or played the same sport, they are ***connected***. In other words, acquainted with each other.

Sergey Brin tells you he'll be back in a few hours to check on your work. You think to yourself *great, he's testing me* :-(. Fresh from your python class at Harvard Extension, you open the lid of your laptop, fire up a jupyter notebook, and dive in!

This is what Sergey Brin is asking you to figure out:

Part 1.

1. a) Read in the three excel files provided as panda dataframes. Hint: you might need to install the xlrd package to get excel support. List Ian Isla's projects, cruises, and sport clubs at Google. Find *one* google employee that is connected with Isla because he or she has been on the same project, cruise, or sport club. **(10 points)**

   b) Find the total number of connections at Google. We define connections as pairs of googlers that worked on a project together, had a cruise together or participated in a sports club together. For example, if Ian Isla and Kaleb Lauren went on a cruise together, then (Ian Isla, Kaleb Lauren) represents a connection. Similarly, if Kaleb Lauren and Roman Valentina played a sport together, then (Kaleb Lauren, Roman Valentina) represents a connection. Furthermore, if Ian Isla and Kaleb Lauren worked on a project together, they have another connection as well. Thus, we have another (Ian Isla, Kaleb Lauren) connection. For this problem, it might help to assign ID's to all your google employees and then loop through projects, cruises and sports to find all possible connections. **(15 points)**

   c) Create a connections dictionary where for each googler, we store a list of all connections they participate in. Using this dictionary, determine the average number of connections per googler. **(15 points)**

   d) Make use of this dictionary to find the most connected googler. What about the 10 *most* connected googlers? What about the 10 *least* connected googlers? What's the total number of connections, and the average number of connections at Google? Note that connections only counts number of projects, cruises, or sports in common. Who one is connected to makes no difference. A connection to Sergey Brin himself counts the same as a connection to a student co-op. **(10 points)**

Now, what if having important connections is of significance? In other words, being connected to Sergey Brin makes a huge difference: if a googler acquaintance you are connected to is *very* connected, that automatically makes you very ***central*** to google. To answer these questions, we need our old friend PageRank.

e) One possible way to tap into PageRank is to use the now-familiar package `networkx`. We want you to create a graph from our connections dictionary. Hint: There are many ways of doing this. One possible way involves hooking into the networkx method `parse_adjlist` that takes in an adjacency list(connections). Look up documentation on this function to learn more. **(10 points)**

f) Use the template from the midterm and previous assignments, or just use networkx's `pagerank()` API that professor mentionned in class to calculate pageRank for google employees. Using this information, find the 10 most central googlers, and the 10 least central googlers. Are they the same as the 10 most and 10 least connected googlers? **(10 points)**

g) BONUS: Can you plot google's connectome? That connectome should easily reveal the least central googlers, since they represent isolated nodes, far away from network traffic. You have some latitude on how you choose to do this. Can you do something to upend that graph to also easily reveal the most central googlers? **(5 points)**

You meet Larry Page

While you're pondering, Larry Page comes by your desk. He says wants to see even more connected googlers, and asks you to design a googler-you-may-know recommendation engine.

You think to yourself that... just maybe googlers might be otherwise (undocumentedly) connected with connections of their connections (outside of projects, cruises, and sports clubs)! So you decide to write some python to assemble connections of connections.

Part 2.

2. a) Write a list comprehension (ideally) or some type of loop to determine connections of connections. Essentially, you should already have a list of connections, but now search the connections of a specific googler to find connections of connections. For example, if (Ian Isla, Kaleb Lauren) were connected in Part 1, and (Kalen Lauren, Roman Valentina) were also connected, then Roman Valentina would be a "connection of a connection" of Ian Isla. While you do this, perform a check to ensure that the connection of a connection should not already be a connection itself. **(20 points)**

   b) What's the average number of connections-of-connections at google? You will be surprised to find out that even with only 3,000 employees, and just a few projects, cruises, and sports in common, the number of connections^2 is huge. So, it would take forever to iterate through all possible employees. DON'T DO THIS. Instead, just use a random sampling technique to *sample* through a fraction of employees, throw in some debugging print statements in your loop(s) to see how fast your sampling is progressing, produce a few random samplings and average over these samplings. We leave it up to you how many samples you decide to choose, and will be lenient with our grading as long as your procedure seems reasonable. **(10 points)**

   c) BONUS: What's the average distance that separates any two googlers? You may want to read this (http://blogs.cornell.edu/info2040/2011/09/26/networks-in-hollywood-the-six-degrees-of-kevin-bacon/) article about Kevin Bacon. This (https://en.wikipedia.org/wiki/Erd%C5%91s%E2%80%93Bacon_number) is a funny article, too. **(5 points)**

Congratulations! A successful first day at Google! You've made both Sergei and Larry happy. You're on your way to the top of the ladder! Exhausted, you escape from your desk before any other VP of soemthing can ask anything else from you, and stop for some sushi and a little jug of warm sake. Tomorrow is new employee orientation, and you're looking forward to introduce yourself to the most connected googlers. Now *that's* taking advantage of insider information!

Solutions: Part 1

Note: **This solution analyzes Question 1 and 2 by partitioning the datasets. See FULL version for solution to Question 1. Each cell here can be executed for demonstration purposes.**

a) Read in the three excel files provided as panda dataframes. Hint: you might need to install the xlrd package to get excel support. List Ian Isla's projects, cruises, and sport clubs at Google. Find *one* google employee that is connected with Isla because he or she has been on the same project, cruise, or sport club. **(10 points)**

b) Find the total number of connections at Google. We define connections as pairs of googlers that worked on a project together, had a cruise together or participated in a sports club together. For example, if Ian Isla and Kaleb Lauren went on a cruise together, then (Ian Isla, Kaleb Lauren) represents a connection. Similarly, if Kaleb Lauren and Roman Valentina played a sport together, then (Kaleb Lauren, Roman Valentina) represents a connection. Furthermore, if Ian Isla and Kaleb Lauren worked on a project together, they have another connection as well. Thus, we have another (Ian Isla, Kaleb Lauren) connection. For this problem, it might help to assign ID's to all your google employees and then loop through projects, cruises and sports to find all possible connections. **(15 points)**

In [281]:

In [282]:

In [283]:

In [320]:

```
Count of Connections from Sports Clubs: 622
Count of Connections from Cruises: 230
Count of Connections from Projects: 90
```

c) Create a connections dictionary where for each googler, we store a list of all connections they participate in. Using this dictionary, determine the average number of connections per googler. **(15 points)**

In [108]:

Out[108]:

```
{'Ian Isla': [['Ian Isla', 'Roman Valentina'],
  ['Ian Isla', 'Christian Alaina'],
  ['Ian Isla', 'Emmett Aurora'],
  ['Ian Isla', 'Angel Addison'],
  ['Ian Isla', 'Jake Arianna'],
  ['Ian Isla', 'George Bella'],
  ['Ian Isla', 'Hudson Melanie'],
  ['Ian Isla', 'Emmett Riley'],
  ['Ian Isla', 'Wesley Athena'],
  ['Ian Isla', 'Ashton Quinn'],
  ['Ian Isla', 'Luca Adriana'],
  ['Ian Isla', 'Aiden Sarah']],
 'Roman Valentina': [['Roman Valentina', 'Emmett Aurora'],
  ['Roman Valentina', 'Hudson Melanie'],
  ['Roman Valentina', 'Emmett Riley'],
  ['Roman Valentina', 'Wesley Athena'],
  ['Roman Valentina', 'Ashton Quinn'],
  ['Roman Valentina', 'Timothy Mckenzie']],
```

In [326]:

```
Average Connections: 9.42
```

d) Make use of this dictionary to find the most connected googler. What about the 10 *most* connected googlers? What about the 10 *least* connected googlers? What's the total number of connections, and the average number of connections at Google? Note that connections only counts number of projects, cruises, or sports in common. Who one is connected to makes no difference. A connection to Sergey Brin himself counts the same as a connection to a student co-op. **(10 points)**

In [327]:

```
Total Connections: 942
Average Connections: 9.42
```

In [297]:

In [298]:

In [328]:

Out[328]:

```
[('Joel Ava', 52),

 ('Micah Morgan', 2),
 ('Thomas Peyton', 2),
 ('Damian Peyton', 1),
 ('George Ruby', 1),
 ('Leonardo Valeria', 1)]
```

Now, what if having important connections is of significance? In other words, being connected to Sergey Brin makes a huge difference: if a googler acquaintance you are connected to is *very* connected, that automatically makes you very ***central*** to google. To answer these questions, we need our old friend PageRank.

e) One possible way to tap into PageRank is to use the now-familiar package `networkx` . We want you to create a graph from our connections dictionary. Hint: There are many ways of doing this. One possible way involves hooking into the networkx method `parse_adjlist` that takes in an adjacency list(connections). Look up documentation on this function to learn more. **(10 points)**

```

Note: We can see that the top and bottom pagerank and connected employee list are different (as we have noticed in class before) in that the top members of pagerank are not the same as the top members with the most connections. Those with connections indirectly others with MORE connections often increases the pagerank more - although there is much overlap between the top ten groups. Given the analogy of Sergey Brin previously - a connection to Sergey Brin at this point raises a person's pagerank more than a connection to a co-op student (assuming the co-op student has very few connections in turn) so it is more of a measure of importance!

g) BONUS: Can you plot google's connectome? That connectome should easily reveal the least central googlers, since they represent isolated nodes, far away from network traffic. You have some latitude on how you choose to do this. Can you do something to upend that graph to also easily reveal the most central googlers? **(5 points)**

In [ ]:

Solutions: Part 2

a) Write a list comprehension (ideally) or some type of loop to determine connections of connections. Essentially, you should already have a list of connections, but now search the connections of a specific googler to find connections of connections. For example, if (Ian Isla, Kaleb Lauren) were connected in Part 1, and (Kalen Lauren, Roman Valentina) were also connected, then Roman Valentina would be a "connection of a connection" of Ian Isla. While you do this, perform a check to ensure that the connection of a connection should not already be a connection itself. **(20 points)**

: [65, 81, 5, 10, 12, 16, 19, 25, 38, 39, 52, 59, 60, 70, 71, 85, 86,
```

b) What's the average number of connections-of-connections at google? You will be surprised to find out that even with only 3,000 employees, and just a few projects, cruises, and sports in common, the number of connections^2 is huge. So, it would take forever to iterate through all possible employees. DON'T DO THIS. Instead, just use a random sampling technique to *sample* through a fraction of employees, throw in some debugging print statements in your loop(s) to see how fast your sampling is progressing, produce a few random samplings and average over these samplings. We leave it up to you how many samples you decide to choose, and will be lenient with our grading as long as your procedure seems reasonable. **(10 points)**

In [340]:

```
Average Secondary Connections (Amongst Everyone): 32.14
Average Secondary Connections (Only Amongst Googlers With Secondary Co
nnections): 32.14
```

Note: in this case everyone has a secondary connection - but that is not neccessarily true!

c) BONUS: What's the average distance that separates any two googlers? You may want to read [this (http://blogs.cornell.edu/info2040/2011/09/26/networks-in-hollywood-the-six-degrees-of-kevin-bacon/)](http://blogs.cornell.edu/info2040/2011/09/26/networks-in-hollywood-the-six-degrees-of-kevin-bacon/) article about Kevin Bacon. [This (https://en.wikipedia.org/wiki/Erd%C5%91s%E2%80%93Bacon_number)](https://en.wikipedia.org/wiki/Erd%C5%91s%E2%80%93Bacon_number) is a funny article, too. **(5 points)**
